Lecture 1

1.1 Books

- Steven H. Strogatz, *Nonlinear Dynamics and Chaos: With Applications to Physics, Biology, Chemistry, and Engineering*, 2nd ed., Westview Press, 2015.

This is Bible for the subject. It is standard, detailed and a bit old text.

1.2 Dynamics

- Study of evolution of systems
Eg. Simple Pendulum

has equation of motion

$$\ddot{\theta} - \frac{g}{l} \sin \theta = 0 \quad (1.1)$$

For small angles

$$\ddot{\theta} - \frac{g}{l} \theta = 0 \quad (1.2)$$

Which is linear. But if θ is not small then non-linear and hence included in NLD¹.

- As equation becomes Non-Linear, the solution drastically changes

¹**NLD:** Non-Linear Dynamics

- Non-Negligible Non-Linear terms are not perturbative and needs separate study
- The subject NLD has advanced after the computers became powerful enough to perform high level computation

1.3 1D Maps

- Suppose we have a sequence of numbers (real numbers mostly)

$$x_0, x_1, x_2, \dots$$

Such that

$$x_0, x_1 = f(x_0), x_2 = f(x_1), \dots \quad (1.3)$$

i.e.

$$x_{n+1} = f(x_n) \quad (1.4)$$

Then it is called an *Map*²

1.3.1 Fixed Point

- Solution of (1.3) such that

$$x^* = f(x^*) \quad (1.5)$$

then x^* ³ is called *fixed point*. Note that it will give rise to the sequence of form

$$x_0, x_1, x_2, \dots, x^*, x^*, x^*, \dots$$

1.3.2 Stability of a Fixed Point

- Suppose $x_0 = \bar{x} + \delta$.

Fig. 1

- Now if the subsequent x 's approach the fixed point x^* then the fixed point is stable and called an *attractor*

²Note here that the function f remains same

³It is widely followed conventions to label fixed point as x^* and we'll continue using it

**Fig. 2**

- Approach to x^* is Oscillatory and is still fixed point

**Fig. 3**

- If the subsequent points diverge from the fixed point (monotonically or oscillatory) then the point x^* is Unstable Fixed Point

**Fig. 4**

1.3.3 Digramatic way to find number of fixed points

Follow the steps:

1. Draw the line $y = x$
2. Draw the curve $y = f(x)$
3. No. of intersections = No. of Fixed Points⁴

Example 1. $f(x) = \sin x$

Fig. 5

There is only one fixed point at $x = 0$

Example 2. $f(x) = \cos x$

⁴This logic is clear from the definition of the fixed point as (1.3.1)

**Fig. 6**

There is only one fixed point at $x \approx 0.74$

Example 3. $f(x) = \frac{2x}{1+x}$

**Fig. 7**

There is only one fixed point at $x = 1$

- In monotonic approach
 $|x_{n+1} - x^*| < |x_n - x^*| \implies$ Stable fixed point
 $|x_{n+1} - x^*| > |x_n - x^*| \implies$ Unstable fixed point
- We define the quantity *multiplier* by

$$\mu = \frac{x_1 - x^*}{x_0 - x^*} \quad (1.6)$$

It determines whether the fixed point is stable or unstable.

$$|\mu| < 1 \implies \text{Stable} \quad (1.7)$$

$$|\mu| > 1 \implies \text{Unstable} \quad (1.8)$$

$$\mu > 0 \implies \text{Monotonic} \quad (1.9)$$

$$\mu < 0 \implies \text{Oscillatory} \quad (1.10)$$

- Now, let's analyze the fixed point analytically. Let

$$x_0 = x^* + \delta \quad (1.11)$$

Then

$$\begin{aligned} x_1 &= f(x_0) = f(x^* + \delta) \\ &= f(x^*) + \delta f'(x^*) + \frac{1}{2}\delta^2 f''(x^*) + \dots \\ &= x^* + \delta f'(x^*) + \frac{1}{2}\delta^2 f''(x^*) + \dots \end{aligned}$$

- Now linearize

$$x_1 = x^* + \delta f'(x^*) \quad (1.12)$$

Therefore,

$$f'(x^*) = \frac{x_1 - x^*}{\delta} = \frac{x_1 - x^*}{x_0 - x^*}$$

Using (1.6)

$$\mu = f'(x^*) \quad (1.13)$$

- Now in Example 1: $\mu = \cos x^* = 1$. The case $\mu = 1$ ⁵ needs special analysis and we skip it for a moment
- In Example 2: $\mu = -\sin(x^*) < 0$, hence fixed point is stable and oscillatory.
- In Example 3:

$$\mu = \frac{2(1+x^*) - 2x^*}{(1+x^*)^2} = \frac{2}{(1+x^*)^2}$$

At $x^* = 0$; $\mu = 2 \implies$ monotonically unstable

At $x^* = 1$; $\mu = 1/2 \implies$ monotonically stable

- Calculating Stability form multiplier is only valid when Linearization is valid.
- We now adopt Diagramatic Approach: *Cobwebb Diagrams*
 1. Draw curve $y = x$
 2. Draw $y = f(x)$

⁵In this case the fixed point x^* is called *Marginally Stable*

3. Draw line from x_0 to $f(x)$
4. Draw horizontal line to $y = x$ and that point of intersection gives x_1

**Fig. 8**

The figure above depicts an example.

Now let's draw Cobweb diagrams to our three examples.

- For Example 1

**Fig. 9**

Note that Cobwebb diagram shows $x = 0$ as stable fixed point unlike our analytical approach which failed due to $\mu = 1$.

- For Example 2

$\mu = 0$ and $\mu = 1$ **Case:**

$$x_1 = x^* + \delta f'(x^*) + \frac{1}{2}\delta^2 f''(x^*) + \dots$$

- for $\mu = 1$

$$\begin{aligned} x_1 &= x^* + \delta + \frac{1}{2}\delta^2 f''(x^*) + \dots \\ &= x_0 + \frac{1}{2}\delta^2 f''(x^*) + \dots \end{aligned} \quad (1.14)$$

hence from above the higher order terms are important and will determine stability.

- For $\mu = 0$

$$\begin{aligned} x_1 &= x^* + \frac{1}{2}\delta^2 f''(x^*) + \dots \\ &\approx x^* + c\delta^2 \quad \left\{ c = \frac{1}{2}f''(x^*) \right\} \end{aligned} \quad (1.15)$$

Now,

$$x_2 = x^* + c(c\delta^2)$$

And hence,

$$x_n = x^* + c^{(\dots)}\delta^{2^n} \quad (1.16)$$

Since convergence is very fast, it is *superstable* fixed point.

-

$$\begin{aligned} x_1 &= f(x_0) = f(x^* + \delta) \\ &= x^* + \delta f'(x^*) + \frac{1}{2}\delta^2 f''(x^*) + \dots \end{aligned}$$

Linearize

$$\begin{aligned} x_1 &= x^* + \delta\mu \\ x_2 &= f(x_1) = f(x^* + \delta\mu) \\ &= x^* + \mu^2\delta \\ x_3 &= \mu^3\delta \\ x_n &= x^* + \mu^3\delta \end{aligned} \quad (1.17)$$

$$\begin{aligned} \frac{x_n - x^*}{x_0 - x^*} &= \mu^n = e^{n \log \mu} \quad (\mu > 0) \\ &= (|\mu| \text{sign}(\mu))^n \\ &= [\text{sign}(\mu)]^n e^{n \log |\mu|} \\ x_n &= x^* + \delta \cdot (\text{sign}(\mu))^n e^{n \log |\mu|} \end{aligned} \quad (1.18)$$

1.4 Logistic Map

We define *Logistic Map*⁶⁷ by

$$f(x) = rx(1 - x) \quad r > 0 \quad (1.19)$$

- Now let's find the fixed points

$$x^* = rx^*(1 - x^*)$$

$$\boxed{x^* = 0} \quad (1.20)$$

$$1 = r(1 - x^*)$$

$$\boxed{x^* = 1 - \frac{1}{r}} \quad (1.21)$$

- We'll always keep $0 \leq |x_n| \leq 1$ and vary $r > 0$
 $x^* = 0$ exist for all r
 $x^* = 1 - \frac{1}{r}$ exist for $r \geq 0$
- Stability of Fixed Points

$$f'(x) = r - 2rx$$

At $x^* = 0$ $f(x^*) = r \implies$ stable fixed point for $r < 1$ and unstable for $r > 1$; $r = 1$ is marginally stable
 At $x^* = 1 - \frac{1}{r}$

$$\begin{aligned} f(x^*) &= r - 2r \left(1 - \frac{1}{r}\right) \\ &= r - 2r + 1 \\ &= 2 - r \end{aligned}$$

for $r = 1$ $\mu = -1$ marginally stable
 for $r = 3$ $\mu = 1$ marginally stable

- for $r > 3$ (say $r = 3.1$) we get sequence

$$x_0, x_1, \dots, p, q, p, q, \dots \quad (1.22)$$

This alternate sequence of p 's and q 's is called a *2-cycle*⁸.

⁶ $f(x)$ is quadratic hence included in NLD

⁷This equations appears in many areas: Engineernig, Population Dynamics, etc.

⁸A fixed point is a 1-cycle
